W. R. "RUSTY" HAIGHT
COLLISION SAFETY INSTITUTE

"Twenty four percent of the frontal crashes that IIHS reviewed in the NASS study were small overlap crashes."

Abstract
A review of small overlap crash test data was conducted during which a seemingly anomalous condition associated with crash severity on the "minor axis" (see note 1) for the vehicles involved in those tests was observed as a function of comparing Event Data Recorder (EDR) and test instrumentation data sets. Where the reconstructionist or researcher might assume that longitudinal and lateral acceleration and/or delta-V would accurately represent the effect on the test vehicle based on past literature in the area, the data reviewed revealed a significant discrepancy between EDR data and the test instrumentation based data. Once the basis for the discrepancy was more fully identified, a corresponding or parallel discrepancy between the EDR data and corresponding values which might be calculated or estimated in a crash analysis or reconstruction was identified.

Over the years, there have been numerous studies (see appendix) on the accuracy and performance of Event Data Recorders (EDRs) in instrumented crash tests. However, most have been focused on full frontal impacts and perpendicular side impacts. This study will shift the focus from full frontal barrier crash tests to small overlap crash tests performed by the Insurance Institute for Highway Safety (IIHS) and the resulting effect this type of collision may have on some of the crash severity data recorded in the EDR component of late model vehicles.

Introduction

In 2009, IIHS published a "Status Report"¹ in which the possibility of creating a new crash test procedure was discussed to analyze vehi-

cle responses to a small overlap crash configuration. Previous similar studies conducted by IIHS focused on moderate (40%) overlap crash tests. The Institute performed a statistical study of real world crashes to evaluate the applicability of the smaller overlap crash test configuration. Researchers used the 2000-2006 National Automotive Sampling System (NASS) Crashworthiness Data System (CDS) to study frontal crashes on US roads. As a result of the study, IIHS Sr. Vice President of Vehicle Research David Zuby said that "[IIHS] found that a lot of frontal crashes are happening in configurations that aren't represented in the crash tests being conducted right now, either by us or the National Highway Traffic Safety Administration."¹

Twenty four percent of the crashes that IIHS analyzed in the study¹ were small overlap crashes where only about twenty five percent of the vehicle is engaged with the impacted object. Mr. Zuby concluded that "based on results of this study, we think small overlap tests have good potential to improve the crashworthiness of new vehicles." The report, along with other technical papers on small overlap crashes provided sufficient justification to further analyze this crash configuration in a laboratory setting. In 2012, IIHS announced that they began testing new vehicles in the small overlap configuration.² By early 2013, IIHS completed testing on eleven mid-sized luxury/near luxury vehicles and eighteen midsized moderately priced vehicles.³ By August of 2013, IIHS completed testing on six small cars in the small overlap crash configuration.⁴

Small Overlap Test Procedure

A brief summary of the IIHS small overlap test will identify data relevant to this study. All the details of the small overlap crash test procedure⁵ is available at the IIHS website (iihs.org). The vehicle is aligned such that 25% of the vehicle width

overlaps with a flat faced rigid barrier with 150 mm radius edge, as shown in Figure 1. The test vehicle is accelerated by a propulsion system to 40 mph (64 km/h) upon impact with the barrier. A fully instrumented 50th percentile Hybrid III Dummy is placed in the driver seat and two pressure-sensitive tape switches placed on the front of the vehicle are used to determine the moment of impact. This time (a “time zero”) is synced with the data acquisition and camera systems.

IIHS also records vehicle acceleration at a location along the longitudinal axis of the vehicle in the rear floorpan. One set of accelerometers, measuring longitudinal, lateral and vertical accelerations are used in each crash test. To ensure the accelerometers stay on axis during the crash, they are mounted to a metal block which is welded to a strong part of the floorpan. Vehicle accelerometers are oriented according to SAE J211⁶. Figure 2 shows the typical location of the accelerometer array relative to the center of

gravity of the vehicle and a target is positioned on the roof of the vehicle over the location of the accelerometer array which can then be seen in later overhead video.

IIHS also captures valuable crash related data from high speed camera footage. Onboard cameras focus on dummy interaction with the vehicle interior while off-board cameras capture vehicle motion and dynamic deformation. All cameras capture 500 frames per second. For this study, the most relevant camera view is the off-board wide overhead angle. Figure 3 shows series of frames captured from a typical small overlap crash test from this “overhead wide” perspective.

Test Results

A group of vehicles from the IIHS small overlap crash testing program were chosen for analysis (see Table I). These vehicles were selected for this study to include many of the available manufacturers supported

Collision Magazine

The International Compendium for Crash Research

is the number one publication for accident reconstruction, safety investigation and crash research.

Over the course of the last 7 years, Collision Magazine has become the preeminent crash reconstruction journal publication providing subscribers with access to timely, relevant and peer-reviewed, thought-provoking reconstruction-related studies and meaningful crash test data from multiple sources. A semi-annual publication, Collision Magazine serves crash reconstructionists from the government and private sectors internationally.

Every issue of Collision Magazine is packed with real, invaluable information on a variety of topics. Included with every issue is a state-of-the-art compendium of the proceedings of either the [APRIL 2011 CDR Summit](#) or the [2010 CDR Summit](#), including presentations, relevant material, crash data, videos, photos, and much more.

Collision Magazine Special Edition #1

Hyundai & Kia Crash Data: The Indispensable Compendium

Limited Press Release

[Read the full press release](#)

Collision Publishing is pleased to announce the first Special Edition of Collision Magazine. This special edition is the first of a series of special editions that will be published throughout the year. This is a limited press release. The special edition is available for purchase or can be requested to be sent to you with your Collision Magazine subscription.

The Special Edition #1 contains the following:

- Hyundai & Kia Crash Data: The Indispensable Compendium
- Hyundai & Kia Crash Data: The Indispensable Compendium
- General
- General

The Special Edition #1 is available for purchase or can be requested to be sent to you with your Collision Magazine subscription. It is an optional special edition pricing. The special edition is available for purchase or can be requested to be sent to you with your Collision Magazine subscription. The special edition price contains both articles in one volume.

The full version of this and other articles from back issues of Collision magazine are available at: <http://www.collisionmagazine.com/>

Influence Dynamic Structural Impact Vehicle Investigation

Author Name: [Name]
Author Address: [Address]

Vehicle investigation is a complex task that requires a thorough understanding of the vehicle's structure and the forces involved in a crash. This article discusses the importance of dynamic structural analysis in vehicle investigation and provides a detailed overview of the process.

Structural analysis is a critical component of vehicle investigation, as it allows investigators to determine the forces and moments that acted on the vehicle during a crash. This article provides a detailed overview of the process of structural analysis and discusses the importance of dynamic structural analysis in vehicle investigation.

Current Issue

Volume 8, Issue 2, Fall 2010
Shipping December 2010
[Click on the link to view the current issue](#)

This issue of Collision features the most detailed and in-depth analysis of Hyundai and Kia crash data published to date. The extensive review of the functionality of the Hyundai/Kia "ECR Tool" application in crash tests and real-world examples is the focus of the primary feature story in the Fall issue of Collision.

In addition, "Differentiating Forensic Cause-Preventive Component Damage from 'Crash Damage'" will get a look at methods for evaluating damaged components and an alternate method of investigating the potential of a pre-crash mechanical failure which may have led to or contributed to a crash. The analysis is carried out by the increasing use of vehicle examinations in "Evidence Collection Overhead" during vehicle investigations. A job of detailed study, these crash investigative techniques allow an examination of crash data in order to help identify and understand the effect of various factors on the contents of the indispensable issue of Collision Magazine.
